About UniStream® Remote I/O

This line of remote Ethernet I/O is compatible with UniStream controllers. The line comprises an Ethernet-based Remote I/O adapter and I/O Remote modules.

You configure Remote I/Os in UniLogic, using the Hardware Configuration editor, and connect them to the controller via Ethernet cable

A single UniStream Remote I/O adapter can support up to 63 12mm wide I/O modules. Each adapter comprises two Ethernet ports; this enables users to link an adapter to a controller, and then daisy-chain adapters to support up to 8 adapters per controller, increasing the total number of I/Os supported by a single UniStream.

UniStream Remote I/O offer a broad range of modules; each module offers a different configuration of analog and digital outputs.

Note that the exact number of I/Os that can be included per adapter is dependent on the specific I/O connected to that specific adapter.

The adapter is limited to process 192 data bytes for inputs and 192 data bytes for outputs.

Each digital input/output point process data is 1 bit (minimum 1 byte per module if module data size is less than 8 points) while each analog input/output is 2 bytes (8 inputs/outputs module will be 16 bytes of process data).

UniStream Remote I/O and Uni-I/O modules

You may use both lines in the same application at the same time.

Since the two lines communicate via different protocols and physical connections:

- They work independently of each other
- You can use both lines with the same controller at the same time.

Note that the adapters and modules of each line are **not** interchangeable.

You may only use:

- Uni-Local Expansion Adapters with Uni-I/O modules
- UniStream Remote I/O Adapters with UniStream Remote I/O modules.

General restrictions

- All examples and diagrams are intended to aid understanding, and do not guarantee operation. Unitronics accepts no responsibility for actual use of this product based on these examples.
- Please dispose of this product according to local and national standards and regulations.
- This product should be installed only by qualified personnel.

Environmental Considerations

- Do not install in areas with: excessive or conductive dust, corrosive or flammable gas, moisture or rain, excessive heat, regular impact shocks or excessive vibration, in accordance with the standards and limitations given in the product's technical specification sheet.
- Do not place in water or let water leak onto the unit.
- Do not allow debris to fall inside the unit during installation.
- Install at maximum distance from high-voltage cables and power equipment.

Dimensions

Installation - DIN-Rail Module Mounting

1. Press down the module lightly on the DIN rail until the lower ridge click onto the rail.

How to Remove the Adapter Module from the DIN-Rail

1. Pull the white locking latch.

2. Pull the module off the rail.

How to remove the RTB (Removable Terminal Block) from the I/O module

1. Pull out the plastic belt from the RTB.

2. Apply more force until the I/O module is pulled away from the I/O module.

How to connect the I/O modules

1. Line up the grooves on the module with the grooves on the adapter (if it is the first module) or on the adjacent module, and slide the module into place as shown in the next image.

Specifications

Items	Specification
Max. Expansion Module	Up to 63 slots The adapter is limited to process 192 data bytes for inputs and 192 data bytes for outputs. Each digital input/output point process data is 1 bit (minimum 1 byte per module if module data size is less than 8 points) while each analog input/output is 2 bytes (8 inputs/outputs module will be 16 bytes of process data).

IP Address Setup using BOOTP Server

The URB adapter IP defaults are:

Default IP: 192.168.100.100

Subnet mask: 255.255.255.0

Note that on the adapter, there is a sticker showing its MAC address.

Editing the IP defaults

There are two methods of changing the IP address:

- Via UniLogic's BOOTP Server
This is a utility accessible via the UniLogic ribbon
- Via DIP switch
These are physical switches on the adapter

Selecting the IP Configuration Method

To enable the selected method, you must raise the appropriate DIP switch on the adapter. By factory default, the adapter is supplied with all switches down.

- Raise #9 to set IP via BOOTP Server:
 - Enables the adapter BOOTP/DHCP.
 - After power up, the adapter will send up to 20 consecutive BOOTP/DHCP request messages, one for every 2 seconds.
 - In case that the BOOTP/DHCP server does not respond, the Adapter applies the latest saved IP address.
- Raise #10 to set IP via DIP switch:
You can then set the IP according to the description in the next table.

Configuring IP using Unitronics BOOTP Server

Before you can set the IP address of the Remote IO adaptor via Unitronics BOOTP Server, you must raise DIP #9 (check that #10 is down)

1. Power OFF the URB adapter.
2. Raise DIP switch #9 to enable DHCP / BOOTP.
3. In UniLogic, in the Solution Explorer, select the adapter; the ribbon will open the tab URB Remote I/O.
4. On the ribbon, click on Run BOOTP Server to open the utility.

5. Click Start BootP in the **Unitronics** BOOTP Server; the upper section displays Ethernet devices that are in the network.

6. Power ON the URB adapter.
7. Locate the adapter's MAC address and double-click on the row.
8. Enter the required IP address and select your PC Network card.

9. Click Ok. Now you should see the device in the bottom window including the IP address.

10. Power cycle the adapter; turn it off and on.

11. Use Ping from command line to check that the IP address is replying.

12. If the adapter replies successfully, then power off the adapter (URB-TCP) and lower DIP switch #9 (set to OFF).

13. Configure the adapter and IO modules in UniLogic and test.

IP Address Setup using BOOTP Server

The URB adapter IP defaults are:

Default IP: 192.168.100.100

Subnet mask: 255.255.255.0

Note that on the adapter, there is a sticker showing its MAC address.

Editing the IP defaults

There are two methods of changing the IP address:

- Via UniLogic's BOOTP Server
This is a utility accessible via the UniLogic ribbon
- Via DIP switch
These are physical switches on the adapter

Selecting the IP Configuration Method

To enable the selected method, you must raise the appropriate DIP switch on the adapter. By factory default, the adapter is supplied with all switches down.

- Raise #9 to set IP via BOOTP Server:
 - Enables the adapter BOOTP/DHCP.
 - After power up, the adapter will send up to 20 consecutive BOOTP/DHCP request messages, one for every 2 seconds.
 - In case that the BOOTP/DHCP server does not respond, the Adapter applies the latest saved IP address.
- Raise #10 to set IP via DIP switch:
You can then set the IP according to the description in the next table.

COMMUNICATION

Device model

Structure of the device model

Communication. This functional unit makes the communication data objects and the associated functionality for data exchange over the CANopen network available. The network status machine is part of this.

Object directory. This contains all the data objects (application data + parameters) that are accessible from outside and that affect the behavior of communication, application and status machines. The object directory is organized as a two-dimensional table in which the data are addressed by their index and sub-index.

The data exchange with CANopen devices takes place by means of data objects. In the CANopen communication profile, two types of standard object (PDO and SDO) and special objects (for network management etc.) are defined. The GN-9261 supports the following objects:

- 32 transmit PDOs
- 32 receive PDOs
- 1 standard SDO (server)
- Node guarding
- NMT objects

Every CANopen device possesses a CANopen object directory in which the parameters for all the CANopen objects are entered.

PDO (Process Data)

Introduction

In many fieldbus systems the entire process image is continuously transferred - usually in a more or less cyclic manner. CANopen is not limited to this communication principle, since the multi-master bus access protocol allows CAN to offer other methods.

The process data in CANopen is divided into segments with a maximum of 8 bytes. These segments are known as process data objects (PDOs). The PDOs each corresponds to a CAN telegram, whose specific CAN identifier is used to allocate them and to determine their priority.

The PDOs are named from the point of view of the Network Adapter: receive PDOs (RxPDOs) are received by the coupler and contain output data, while transmit PDOs (TxPDOs) are sent by the coupler and contain input data.

PDO Mapping

CANopen specifies the data assignment for the first two PDOs in the device profile for input/output groups (DS401) (“default mapping”). The first PDO is provided for digital inputs (TxPDO1) or outputs (RxPDO1). The first 4 analog inputs or outputs are located in the second PDO. These PDOs are accordingly occupied by the Network Adapters - if, for instance, no digital output terminals are plugged in, RxPDO1 remains empty.

Once the first PDOs have been occupied, the next PDOs are filled with process data in the following sequence:

1. Digital I/O (1-byte)
2. Digital I/O (2-byte)
3. Analog I/O

PDO Identifier

For the first two PDOs (PDO1 + PDO2) CANopen provides default identifiers depending on the node address, but all other PDOs must have identifiers assigned to them. The principle of the default identifiers is explained in the section on “Network Management”, and there is a list of all the CANopen default identifiers in the appendix.

Pre-Define Connection Set

In the system of default identifiers, all the nodes (here: slaves) communicate with one central station (the master), since slave nodes do not listen by default to the send identifier of other slave nodes:

PDO Linking

If the consumer-producer model of CANopen PDOs is to be used for direct data exchange between nodes (without a master), the distribution of identifiers must be appropriately adapted, so that the TxPDO identifier of the producer agrees with the RxPDO identifier of the consumer:

This procedure is known as PDO linking. It permits, for example, easy construction of electronic drives in which several slave axes simultaneously listen to the actual value in the master axis TxPDO.

PDO Communication Type

Event driven

The “event” is the alteration of an input value, the data being transmitted immediately after this change. The event-driven flow can make optimal use of the bus bandwidth, since instead of the whole process image it is only the changes in it that are transmitted. A short reaction time is achieved at the same time, since when an input value changes it is not necessary to wait for the next interrogation from a master.

Polling

The PDOs can also be polled by data request telegrams (remote frames). In this way it is possible to get the input process image of event-driven inputs onto the bus, even when the inputs have not changed, for instance by a monitoring or diagnostic device brought into the network while it is running.

The Crevis CANopen bus Adapter supports the interrogation of PDOs by means of remote frames.

Synchronized

It is not only for drive applications that it is worthwhile to synchronize the determination of the input information and the setting the outputs. For this purpose CANopen provides the SYNC object, a CAN telegram of high priority but containing no user data, whose reception is used by the synchronized nodes as a trigger for reading the inputs or for setting the outputs:

PDO transmission type

The “PDO transmission type” parameter specifies how the transmission of the PDO is triggered, or how received PDOs are handled:

Transmission type	PDO transmission				
	cyclic	acyclic	synchronous	asynchronous	RTR only
0		X	X		
1-240	X		X		
241-251	reserved				
252			X		X
253				X	X
254				X	
255				X	

Synchronous

Transmission type 0 is only useful for RxPDOs: the PDO is only used when the next SYNC telegram is received. In transmission types 1-240 the PDO is cyclically transmitted or expected: after every “nth” SYNC (n = 1...240).

Since transmission types can be combined on a coupler as well as in the network, it is possible, for example, for a fast cycle to be agreed for digital inputs (n = 1), whereas the data for analog inputs is transmitted in a slower cycle (e.g. n = 10). The cycle time (SYNC rate) can be monitored (object 0x1006), so that if the SYNC fails the Adapter switches its outputs into the fault state.

Asynchronous

The transmission types 254 + 255 are asynchronous, but may also be event-driven. In transmission type 254, the event is specific to the manufacturer, whereas for type 255 it is defined in the device profile. Since the Beckhoff CANopen Network Adapters support device profile DS401 no distinction is made here between the two transmission types.

Inhibit Time

The “inhibit time” parameter can be used to implement a “transmit filter” that does not increase the reaction time for relatively new input alterations, but is active for changes that follow immediately afterwards. The inhibit time (transmit delay time) specifies the minimum length of time that must be allowed to elapse between the transmission of two of the same telegrams. If the inhibit time is used, the maximum bus loading can be determined, so that the worst case latency can then be found.

SDO (Service Data)

Introduction

The parameters listed in the object directory are read and written by means of service data objects. These SDOs are multiplexed domains, i.e. structures of any size that have a multiplexer (address). The multiplexer consists of a 16-bit index and an 8-bit sub-index that address the corresponding entries in the object directory.

The CANopen Network Adapters are servers for the SDO, which means that at the request of a client they make data available (upload), or they receive data from the client (download).

This involves a handshake between the client and the server. When the size of the parameter to be transferred is not more than 4 bytes, a single handshake is sufficient (one telegram pair).

For a download, the client sends the data together with its index and sub-index, and the server confirms reception. For an upload, the client requests the data by transmitting the index and sub-index of the desired parameter and the server sends the parameter (including index and sub-index) in its answer telegram. The same pair of identifiers is used for both upload and download. The telegrams, which are always 8 bytes long, encode the various services in the first data byte.

All parameters with the exception of objects 1008h, 1009h and 100Ah (device name, hardware and software versions) are only at most 4 bytes long, so this description is restricted to transmission in expedited transfer.

Emergency (Error Message)

Emergency messages are always sent in the event of a critical error situation having occurred/overcome in the device, or if important information has to be communicated to other devices.

Structure and meaning of the entries in the emergency object are explained in the table .EMCY-CODE., they are coded in the bus message in a 'Low byte' / 'High byte' order.

An emergency object is also sent, after an error is remedied (Error Code = 0x0000, the Error Register and the Additional Code behave as described in the table .EMCY-CODE.).

Following Power On an emergency object is sent if the loaded settings are the default settings. This occurs for two reasons:

- No settings have yet been saved (Index 0x1010).
- The saved setting was discarded by the Network Adapter, because modules were connected or disconnected.

NMT (Network Management)

Network Start-up

CANopen defines a state machine that controls the functionality of a device. Transition between the individual states is initiated by internal events or services from the NMT master. These devices states can be connected to application processes.

In **Initialization** state, the CANopen data structures of a node are initialized by the application. The CiA DS-301 standard defines various mandatory OD entries for this task as well as specific communication objects required for that. In the minimum device configuration, the identifier for these communication objects must correspond to the so-called **Pre-Defined Connection-Set**. The device profiles define further settings for the applicable device class. The pre-defined settings for identifier for emergency, PDOs and SDOs are calculated based on the node address (Node ID) that can be in the range from 1 to 99, added to a base identifier that determines the function of the individual object. After **Initialization** is completed the node automatically switches into **PRE-OPERATIONAL** (12) state. The NMT master will be informed about this state change with the BOOT-UP message sent by the corresponding node. In this state it is not possible to communicate with the node using PDOs. However, the node can be configured over the CAN bus using SDOs in **PRE-OPERATIONAL** state. NMT services and Life Guarding are also available in this state.

The application as well as the available resources of the CANopen device determine to what extent configuration over the CAN bus with the help of SDOs must take place. For example, if the CANopen device does not provide a non-volatile memory to store mapping and communication parameters for PDOs and these parameters differ from the default values, then these parameters must be transmitted to the node over the network after initialization is completed.

After the configuration of these parameters by the application or the NMT master is completed, the NMT service *Start_Remote_Node* (6) can be used to render the node from **PRE-OPERATIONAL** state into **OPERATIONAL** state. This state change also causes the initial transmission of all TPDOs independently of whether an event for it is present. Each subsequent transmission of PDOs then always takes place as a function of an event.

All CANopen devices also support the *Stop_Remote_Node* (7), *Enter_PRE-OPERATIONAL_State* (8), *Reset_Node* (10), *Reset_Communication* (11) services. *Reset_Node* is used to reset the application-specific data and the communication parameter of the node. The CANopen data structures are loaded with their initial values. Data stored in a non-volatile memory are rejected. This state change is comparable with an initial operation of the node.

If the NMT service *Reset_Communication* is used to change the state of a node, then loading initial values exclusive for the communication parameters in the CANopen stack takes place.

No communication via PDO and SDO is possible if the device is in **STOPPED** state. Only NMT services, Node Guarding, Life Guarding as well as Heartbeat are possible in this state.

Boot-up Message

After the initialization phase and the self-test, the Network Adapter sends the boot-up message, a CAN message with no data bytes and with the identifier of the emergency message: CAN-ID = 0x80 + node ID.

Node Guarding

Node Guarding represents a means of node supervision that is initiated by the NMT master. This service is used to request the node's operational state and to determine whether the node is functioning correctly. The NMT master transmits a single Node Guard message to the slave in the form of a remote frame with the CAN identifier 0x700 plus the node address of the NMT slave. As a response to this remote frame, the NMT slave sends a CAN message back containing its current NMT state and a one bit that toggles between two subsequent messages.

Response from the NMT Slave to a Node Guard Remote Frame:

Identifier	DLC	Data
		0
0x700 + Node Address	1	Status Byte

Node State of a CANopen Device

Status Byte	Node State
0x00	BOOT-UP
0x04	STOPPED
0x05	OPERATIONAL
0x7F	PRE-OPERATIONAL

Bit 7 of the status byte always starts with a 0 and changes its value after each transmission. The application is responsible for actively toggling this bit. This ensures that the Node Guard response message from a slave is not just stored in one of the Full-CAN channels. Thus the NMT master will get the confirmation from the NMT slave node that the application is still running.

Life Guarding

As an alternative to Node Guarding node supervision can also be performed by Life Guarding services. In contrast to the Node Guarding the NMT master cyclically sends a Life Guard message to the slave in the form of a remote frame with the CAN identifier 0x700 plus the node address of the NMT slave. As a response to this remote frame, the NMT slave sends a CAN message back containing its current NMT state and a one bit that toggles between two subsequent messages. With being missing the answer or unexpected status of the slave the NMT masters application is informed. Further the slave can detect the loss of the masters. The Life Guarding is started with the transmission of the first Life Guard message of the masters.

Response from the NMT Slave to a Life Guard Remote Frame

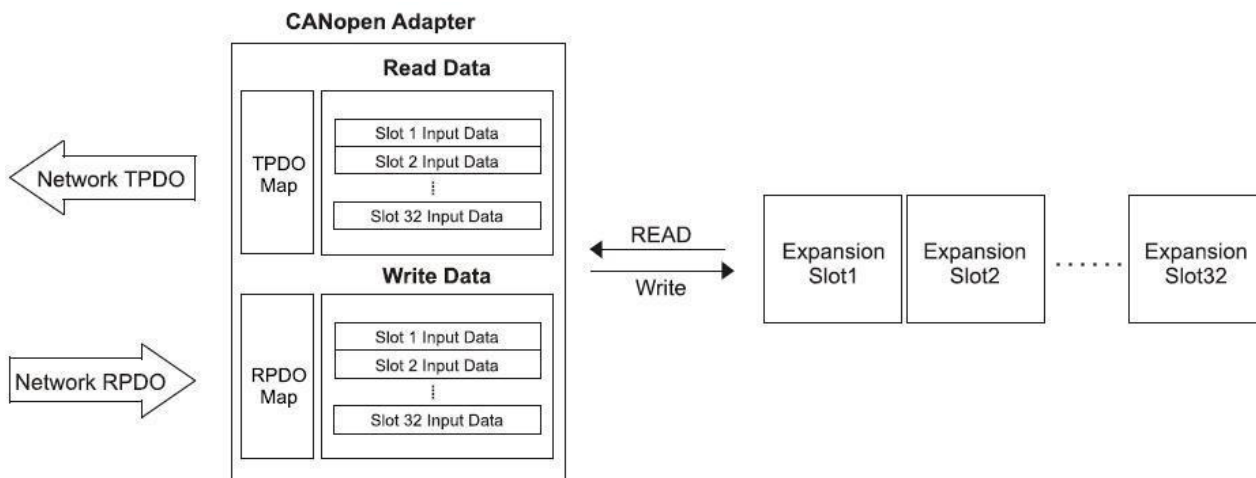

Identifier	DLC	Data
		0
0x700 + Node Address	1	Status Byte

Meaning of the status byte corresponds to that of the Node Guarding message The Life Guarding supervision on the NMT slave node is deactivated, if the Life Guard time (object entry 0x100C in the object dictionary) or the Life time factor (object entry 0x100D in the object dictionary) are equal to zero.

I/O Process Image Map

An expansion module may have 3 types of data as I/O data, configuration parameter and memory register.

The data exchange between network adapter and expansion modules is done via an I/O process image data by FnBus protocol. The following figure shows the data flow of process image between network adapter and expansion modules.

Absence of network adapter	Off	Network adapter is not connected to this module.

3. Use Scenario

- URP-PS24V is system internal power expansion module.
- The URB-TCP network adapter system supplies a current of 1.5A. If your system current requirements exceed 1.5A, add a power supply such as the URP-PS24V.
- Position the power supply directly before the first module that will cause the requirement to exceed 1.5A, as shown in the example below.

3. Use Scenario

Field Power	
URB-TCP	10A max.
URB-TCP2	8A max.
URP-PDIST	10A max.

- Each URB series output unit can provide specified amount of current to connected end devices like: contactors, solenoids, sensors and etc.
- In case that the calculated required field power consumption exceeds the maximal provided current by the network adapter, URP-PDIST module must be added.

For example:

URD-0008CH can provide 0.5A per channel, total of 4A per module.

URD-04PW can provide 0.5A per channel, total of 2A per module.

So if the system have 2 X URD-0008CH and 1 X URD-04PW attached directly to the network adapter and all channels current usage it the maximal allowed, we need to add URP-PDIST is additional output modules attached.
